A Non Spiraling Integrator for the Lotka Volterra Equation

Martin J. Gander

Abstract

We consider the solution of the Lotka Volterra System of differential equations in \( \mathbb{R}^2 \). Most numerical methods in use exhibit spiraling, although the exact solution is cyclic. We show, how a simple modification of the Forward Euler method leads to cyclic solutions in the numerical approximation.

1 The Lotka Volterra Equations

We consider a predator species \( y \) and its prey \( x \). The Lotka Volterra system of differential equations describes the evolution of \( x \) and \( y \) by

\[
\begin{align*}
\dot{x} &= x - xy \quad ; \quad x(0) = \hat{x}, \\
\dot{y} &= -y + xy \quad ; \quad y(0) = \hat{y}.
\end{align*}
\]

(1)

The growth rate of the prey population \( \dot{x} \) is proportional to the current population \( x \) minus the number of prey predator encounters, proportional to \( xy \). The growth rate of the predator population \( \dot{y} \) is proportional to the predator prey encounters \( xy \) minus the current population \( y \). A derivation of this system can be found in Hirsch [2], or in the original paper by Volterra [6].

2 Exact Solution

It is well known, that the solution to (1) is cyclic for all initial values \( \hat{x}, \hat{y} \) in the first quarter plane. The cycles are around the equilibrium point \( \bar{x} = 1 \), \( \bar{y} = 1 \), which is obtained by setting the time derivatives on the left hand side of (1) equal to zero. However explicit solutions
Figure 1: Exact solution of the Lotka Volterra System

to this system of equations have only recently been found by Steiner [5]. The explicit solution is given in parametric form,

\[
\begin{align*}
x &= \frac{1}{2} \tau \pm \frac{1}{2} \sqrt{\tau^2 - 4Ce^\tau}, \\
y &= \frac{1}{2} \tau \mp \frac{1}{2} \sqrt{\tau^2 - 4Ce^\tau},
\end{align*}
\]

where the constant \( C \) is given by

\[ C = \hat{x} \hat{y} e^{\hat{x} + \hat{y}}. \]

Figure 1 shows the solution for initial values \( \hat{x} = 0.5 \) and \( \hat{y} = 0.5 \).

3 Forward Euler Method

The Forward Euler method discretizes the time derivative in equation (1) by a forward difference. We get the discrete system at time \( t_n \)

\[
\begin{align*}
\frac{x_{n+1} - x_n}{\Delta t} &= x_n - x_n y_n \quad ; \quad x_0 = \hat{x}, \\
\frac{y_{n+1} - y_n}{\Delta t} &= -y_n + x_n y_n \quad ; \quad y_0 = \hat{y}.
\end{align*}
\]

(2)
This is an explicit iteration formula. The solution obtained with a time step $\Delta t = 0.1$ and initial values $\hat{x} = 0.5$, $\hat{y} = 0.5$ together with the exact solution is shown in Figure 2. The numerical solution obtained by Forward Euler exhibits spiraling, and this is the case for most numerical methods (cf Golub [1]). A rare example of a non-spiraling method is Kahan’s unconventional numerical method [3]. We show in the next section how a simple modification to the Forward Euler approximation leads to a non spiraling method.

4 Modified Forward Euler Method

The modification we make is rather simple. We replace $x_n$ in the product term of the second equation of (2) by its newest value $x_{n+1}$ to get the numerical iteration

\[
\begin{align*}
\frac{x_{n+1} - x_n}{\Delta t} &= x_n - x_n y_n; \quad x_0 = \hat{x},
\end{align*}
\]

\[
\begin{align*}
\frac{y_{n+1} - y_n}{\Delta t} &= -y_n + x_{n+1} y_n; \quad y_0 = \hat{y}.
\end{align*}
\]

(3)
The idea of this change comes from numerical linear algebra, where one calls the iteration in (2) the Jacobi iteration and the modified one in (3) the Gauss Seidel iteration. Figure 3 shows the solution obtained with the modified Forward Euler method with time step $\Delta t = 0.1$ and initial values $\dot{x} = 0.5$, $\dot{y} = 0.5$. The exact solution is plotted as a dashed curve. Note that the modified Forward Euler method is still explicit.

### 5 Proof of Cyclic Behavior

Note that (1) can be written as

$$
\begin{align*}
\dot{x} &= -xy \frac{\partial H}{\partial y}; \quad x(0) = \bar{x}, \\
\dot{y} &= x y \frac{\partial H}{\partial x}; \quad y(0) = \bar{y}
\end{align*}
$$

with the function

$$H(x, y) = x + y - \ln x - \ln y.$$
Therefore (4) is a non-standard Hamiltonian system. It would be Hamiltonian, if the factor $xy$ was not present in (4). By Liouville’s theorem, Hamiltonian systems are area preserving; they preserve the quantity $dx \wedge dy$. By the KAM theory [4], a numerical integration scheme does not spiral if it preserves the same quantity $dx \wedge dy$. In our non-standard Hamiltonian case, there is a similar quantity preserved, as the following theorem shows.

**Theorem 1** The system (4) preserves the weighted area $(dx \wedge dy)/xy$.

**Proof:** Let $\Omega_0$ be a subset of $\mathbb{R}^2$ at time $t_0$ and $\Omega_1$ the set into which $\Omega_0$ is mapped by (4) at time $t_1$, as shown in Figure 4. Preservation of $(dx \wedge dy)/xy$ is equivalent to

$$\int_{\Omega_0} \frac{1}{xy} \, dx \, dy = \int_{\Omega_1} \frac{1}{xy} \, dx \, dy.$$ 

We now look at the domain $D$ in $x$, $y$, $t$ space with the boundary $\partial D$ given by $\Omega_0$ at $t_0$, $\Omega_1$ at $t_1$ and the set of trajectories emerging from the boundary of $\Omega_0$ and ending on the boundary of $\Omega_1$. Consider the vector field

$$v := \frac{1}{xy} \begin{pmatrix} \dot{x} \\ \dot{y} \\ 1 \end{pmatrix}.$$
in $x$, $y$, $t$ space. Integrating this vector field over the boundary $\partial D$ of $D$, we obtain

$$\int_{\partial D} v \cdot n = \int_{\Omega_0} v \cdot n_0 + \int_{\Omega_1} v \cdot n_1 = \int_{\Omega_0} \frac{1}{xy} \, dx \, dy - \int_{\Omega_1} \frac{1}{xy} \, dx \, dy,$$

where $n_0 = (0, 0, -1)^T$ and $n_1 = (0, 0, 1)^T$ denote the unit outward normal of $\Omega_0$ and $\Omega_1$. There is no other contribution to the surface integral, because the vector field $v$ is by construction parallel to the trajectories, which form the rest of the boundary $\partial D$. Applying the divergence theorem to the left hand side of the same equation, we get

$$\int_{\partial D} v \cdot n = \int_D \nabla \cdot v = \int_D -\frac{\partial H^2}{\partial x \partial y} + \frac{\partial H^2}{\partial x \partial y} + 0 = 0,$$

which concludes the proof.

**Theorem 2** The modified Euler scheme (3) preserves the weighted area $(dx \wedge dy)/xy$. Therefore the numerical solution does not spiral.

**Proof:** To simplify notation, we rewrite one step of (3) as

$$X = \Delta tx + x - \Delta t xy$$
$$Y = -\Delta ty + y + \Delta t X y,$$

where we have set $X := x_{n+1}$, $Y := y_{n+1}$, $x := x_n$ and $y := y_n$, and solved for the unknowns $X$ and $Y$. Taking derivatives of both sides, we get

$$dX = \Delta t dx + dx - \Delta t dx y - \Delta t x dy$$
$$dY = -\Delta t dy + dy + \Delta t X y + \Delta t X dy.$$

Now we can compute the wedge product $dX \wedge dY$. We obtain, after some manipulation, observing that $dX \wedge dX = 0$ and $dY \wedge dY = 0$,

$$dX \wedge dY = dx \wedge dy \left( \Delta t^3 (x - 2xy + xy^2) + \Delta t^2 (-1 + 2x + y - 2xy) + \Delta t (x - y) + 1 \right).$$
But the product of $X$ and $Y$ is

$$XY = xy\left( \Delta t^3(x - 2xy + xy^2) + \Delta t^2(-1 + 2x + y - 2xy) + \Delta t(x - y) + 1 \right),$$

and therefore, we have

$$\frac{1}{XY} dX \wedge dY = \frac{1}{xy} dx \wedge dy$$

and our scheme preserves the weighted area.
