

**COMMUNIQUÉ
DE PRESSE**Geneva, November 1st 2022**Antiphospholipid Syndrome****A NEW TEST FOR DETECTING THE
ANTIBODIES RESPONSIBLE FOR
THROMBOSES AND MISCARRIAGES**

The Geneva University Hospitals (HUG), the University of Geneva (UNIGE) and their spin-off Endotelix have created the best possible target molecule for the antibodies responsible for antiphospholipid syndrome. This discovery will enable a new screening test to be developed. This auto-immune syndrome leads to the thromboses responsible for strokes and heart attacks. It has a serious impact on pregnant women, and can cause the death of their foetuses. The limited reliability of the current screening tests means that diagnostics cannot be performed before the first clinical signs appear. The new approach on the part of the HUGs and Endotelix increases the likelihood of the syndrome being detected from 40% to 85%, and finally opens up the door to screening. You can find out more in [Research and Practice in Thrombosis and Haemostasis](#).

Antiphospholipid syndrome (APS) is an auto-immune disease that can cause miscarriages or the death of the foetus. Antibodies turn against certain proteins (phospholipids, fatty substances that are essential for the organism's survival) located on the surface of cells or circulating in the blood. These antibodies are called antiphospholipids.

While one study¹ estimates that the antiphospholipids are responsible for an APS in 50 to 100 people out of 100 000, experts put the prevalence at 1 to 5% of the global population. For every man affected, four women are affected. This auto-immunity creates clots that are responsible for thromboses and can disrupt the pregnancy. At least 15% of recurring miscarriages are due to a case of APS. APS is now recognised as the most easily avoidable cause of miscarriages².

"This syndrome is also very problematic prior to the pregnancy for women who desire a contraception. The cocktail of the APS and the hormonal pill causes infertility in 90% of cases within ten years," warns François Mach, head doctor at the HUGs' Cardiology Department, professor in the Department of Medicine at the UNIGE's Medicine Faculty and co-author of the study.

While indirect treatments exist (chronic taking of anticoagulants), a reliable screening test would take effect before any dramatic consequences occur.

A quick and reliable test

The current tests have only 40% sensibility for antiphospholipids, "which amounts to a coin-toss", notes Karim Brandt, a former member of the scientific staff at the UNIGE's Medicine Faculty and Director of Science at Endotelix, who is responsible for the study. "That's why the tests currently need to be correlated with clinical facts in order for an accurate diagnosis of APS to be made," he adds. It's a problematic situation given the seriousness of the clinical symptoms.

His team managed to develop a new test that is a hundred times finer, making the sensibility rise to 85%. This level of sensibility is sufficient to be able to offer a rapid test, like the antigen tests for COVID-19. It is mainly aimed at screening for women wanting a pregnancy or hormonal contraception, and will make it possible to prescribe treatments or appropriate care paths.

Finding the best target

We still don't have a good understanding of the origins of APS, aside from knowing that, for unknown reasons, antiphospholipids are present in the blood. Immunologists also know one of its targets: a circulating glycoprotein known as Beta2GP1.

The strategy used by Karim Brandt's team to develop this diagnostic test was to identify, as specifically as possible, the region of the Beta2GP1 that is targeted by the antiphospholipids. Their idea was to imitate the properties of this region by creating a fictitious molecule that was as similar as possible to the antiphospholipids, i.e. the quest for the perfect target for these antibodies.

His team set about analysing 600 molecules (peptides with different sequences of amino acids) showing similarities with the region of the Beta-2GP1 in the presence of antiphospholipids stemming from male and female patients. A molecule with sixty times more affinity for antiphospholipids than the target region of the Beta-2GP1 was thus found.

A synthetic antibody directed against the Beta-2GP1 was then created in the laboratory, thanks to this molecule. Allied to the ELISA biochemical analysis technique, it allows for a quantitative dosage and a very useful standardization of measures, synonymous with a high degree of reliability.

A study that will be of use for treatments

A test for research is already available and a clinical study in humans is in progress. If it succeeds, the expectation is that it will be put on the market in the near future. A rapid screening kit is currently being designed, moreover, with the partners at the National Centre for Scientific Research (CNRS) in Lyon. "Since the sequence of

amino acids has a high capacity for interaction with antiphospholipids, it could also serve as a direct inhibitor via monthly or bimonthly injections in the guise of treatment," Karim Brandt concludes.

Les HUG : soins, enseignement et recherche de pointe

Les Hôpitaux universitaires de Genève (HUG) rassemblent huit hôpitaux publics et deux cliniques. Leurs missions sont de prodiguer les soins à la communauté dans toutes les spécialités médicales, de contribuer à former les médecins et professionnel·les de la santé et d'effectuer des recherches médicales et soignantes. Les HUG sont centre national de référence pour l'influenza et les infections virales émergentes, ainsi que pour les maladies du foie de l'enfant et la transplantation hépatique pédiatrique. Ils sont centre collaborateur de l'OMS dans cinq domaines. En 2020, avec leurs 13'557 collaborateurs·trices, les HUG ont accueilli 56'761 cas hospitaliers, assuré 190'825 entrées aux urgences, 1'074'645 de prises en charge ambulatoires, 22'409 interventions chirurgicales et 4'020 naissances. 1'093 médecins internes et chef·fes de clinique, 2'760 stagiaires et 200 apprenti·es y effectuent leur formation. Les HUG collaborent étroitement avec la Faculté de médecine de l'Université de Genève, l'OMS, le CHUV, l'EPFL, le CERN et d'autres acteurs de la Health Valley lémanique à différents projets de formation et de recherche. Le budget annuel des HUG est de 2.14 milliards de francs.
